Introduction

The decennial population census is the only source of information about population growth in the districts of the country. India had an unbroken series of decennial population census for 120 years - from 1881 to 2011 - which was unparalleled among the developing countries. This continuity is now broken as the 2021 decennial population census could not be conducted because of the COVID-19 pandemic. The fall-out is that estimates of the population of the districts of the country are not available after 2011. The Government of India has projected the population of the country and the population of its constituent states and Union Territories for the period 2011-2036 based on the data available from the 2011 population census (Government of India, 2020) but no such exercise has been carried out for the districts. Updating and forecasting district population estimates is the need of the time as they are required for many purposes including district development planning and programming, provision of welfare services such as health and education services, infrastructure development, making decisions about investment in the district, and assessing the future development and welfare needs of the people. Since, the population growth trajectory of different districts is essentially different, a district wide approach is needed for modelling and forecasting district population. There has, however, never been any attempt to model district population growth in India. One reason is that there have been frequent changes in the administrative boundaries of districts. At the 1951 decennial population census, there were only 316 districts in the country. This number increased to 640 at the 2011 decennial population census. Modelling district population growth requires that administrative boundaries of the district remain unchanged.

Attempts to project or forecast population of districts in India are rare. Since 1958, the Government of India regularly constitutes an expert committee or a technical group after every decennial population census to project the population of the country for the next 25 years. These committees or expert groups have, however, been confined to projecting the population of the country and its constituent states and Union Territories. There has never been any attempt to project population of districts. The first attempt to project the population of the districts of the country was made by the United Nations Population Fund in 2009. However, this exercise did not cover all districts of the country as they existed in 2009 but was confined to selected states only (UNFPA, 2009). It is only recently, that there has been an attempt to project population of all districts of India (Dhar, 2022). Both attempts are based on the ratio method which expresses the population of a smaller area as a proportion of the population of a larger area. Ratio methods are mostly used where there is a perfect hierarchical structure

Modelling and Forecasting Population Growth

or where the smaller units are mutually exclusive and exhaustive and can be aggregated to equal the larger unit. One requirement of the ratio method is the availability of an independent projection of the population of the larger unit (Smith et al, 2013). The approach followed in both the studies may also be termed as the top-down approach in which projections are first made for the state or the Union Territory concerned and then the projected population of the state or the Union Territory is apportioned into constituent districts of the state or the Union Territory. This approach pays no attention to the population dynamics specific to the district which may be different from the population dynamics of the state or the Union Territory to which the district belongs. The implicit assumption behind the ratio method is that the population growth pattern that prevails in a district is the same as the population growth pattern that prevails in the state or the Union Territory to which the district belongs. This assumption is, however, difficult to justify. The population growth pattern in the state or the Union Territory is determined by the population growth pattern in the districts that constitute the state or the Union Territory, but the reverse is not true. It is obvious that any approach to project or forecast the population of a district must consider the population dynamics specific to the district. Population projection or forecast of the population of a district based on the population dynamics specific to the district also constitutes what is known as the bottom-up approach of population projection or forecasting. In the bottom-up approach, the projection or forecast of the population of the smallest area is produced first and then projection or forecast of the population of larger areas is simply the sum of the projected or forecasted population of the smaller areas that constitute the larger area. The major problem with the use of the bottom-up approach, however, is characterising the population growth dynamics of smaller areas. The data required for characterising the population growth dynamics of smaller areas are generally not available.

The Registrar General and Census Commissioner of India has recently made available population of 640 districts of the country, as they existed at the times of the 2011 population census, for the period 1901-2011 based on different decennial population census conducted in the country since 1901. This district population dataset, spanning a period of more 110 years, provides, for the first time, an opportunity to characterise population growth in each of the 640 districts of the country which may be used to project or forecast the population of the district. The district population or forecast may then be added to obtain population projection or forecast for the states and Union Territories and then for the country. This approach of population projection or forecasting is based on the population growth dynamics of the 640 districts of the country.

Projecting or forecasting district population is essentially an exercise in small area population projection or forecasting. Different methods of small area population projection or forecasting have been proposed. A comprehensive review of these methods is given elsewhere (Wilson et al, 2022). These methods can be grouped in the following eight categories: 1) extrapolative and comparative methods; 2) simplified cohort-component methods; 3) methods of model averaging and combining; 4) methods based on the relationship with socioeconomic and spatial variables; 5) housing led population projections; 6) downscaling and disaggregation approaches; 7) small area microsimulation; and 8) machine learning. Data requirement for different methods are different and is a key consideration in the selection of the method. Simple extrapolative models have historically been used for small area population forecasting (Pritchett, 1891; Pearl and Reed, 1920; Schmitt and Crosetti, 1951; White, 1954; Isserman, 1977; Openshaw and Van Der Knaap, 1983; Smith, 1987). The advantage of these methods is that the data requirement for their application is minimal, and their accuracy is often at par with more complex methods (Smith et al, 2013). On the other hand, comparative methods project or forecast population of small areas based on a relationship with an independent projection or forecast of

the population of a larger area that comprises of the small areas. These methods are also known as ratio methods. Both extrapolative methods and comparative or ratio methods, generally project or forecast total population instead of projecting or forecasting age- and sex-specific population, although the two methods can be combined to project or forecast age- and sex-specific population (Siegel and Swanson, 2004).

Although the terms ‘projection’ and ‘forecast’ are interchangeably used in the literature, it is important to distinguish between the two. A forecast is the most likely outcome whereas a projection is essentially a hypothetical scenario (Smith et al, 2013). A projection is the outcome of a particular set of assumptions about the future trend. If this set of assumptions is changed, the projection will change. As such, a projection is always a conditional statement, contingent upon the set of assumptions on which it is based. The projection shows what would be the future if a particular set of assumptions hold true. The projection, however, makes no prediction as to whether the set of assumptions will actually hold true or not. If this set of assumptions is changed, the projection will change. A projection, therefore, can never be proved wrong by the future trend. If the projected trend is found to differ from the actual trend, then this may be because one or all the assumptions on which the projection is based could not be realised. An advantage of projection, however, is to have different projections based on different set of assumptions about future trend. This helps in future scenario analysis. A projection may also be perceived as an exercise in supervised learning as the assumptions behind the projection are set in advance and are subject to modification or change. Setting the assumptions behind a projection in advance introduces some degree of subjectivity in every projection.

A population forecast, on the other hand, is the most likely prediction of the future that is contingent upon the past trend. Contrary to the projection, which is non-judgmental, a forecast is explicitly judgmental. Unlike the projection, which is conditional upon assumptions regarding future trend, a forecast is conditional upon the past dynamics. If the past dynamics is characterised or modelled accurately, then, future can be forecasted by just extrapolating the model describing the past trend. A forecast, therefore, shows the most likely future under the assumption that the past pattern will continue to hold in the future also. This means that an accurate characterisation or modelling of the past trend serves the basis for forecasting at a future date. However, if the past trend does not hold in the future, then the forecast will also differ from the actual trend. A forecast may be perceived as an exercise in unsupervised learning as the past trend cannot be modified or changed. Unlike projection, there is no subjectivity in forecast as the model used for extrapolation depends entirely upon the past data which cannot be changed. The challenge in forecasting, however, is to accurately characterise of model the past trend. If there is no consistency in the past trend, then modelling past trend and hence extrapolation for the future may be quite erratic. A population forecast and a population projection may yield similar results if the past population growth dynamics is modelled correctly and if the assumptions on which the population projection is based are realistic. When the focus is on estimating the most likely future population, forecast is preferred over projection. On the other hand, when the focus is on analysing alternative scenarios of future population growth, projection is preferred as different projections can be made from the same set of data under different set of assumptions.

In this monograph, we first model population growth during the period 1951-2011 in each of the 640 districts of the country, as they existed at the time of the 2011 decennial population census. This modelling is possible, for the first time, as the population estimates of these 640 districts are now available for the period 1901-2011 at an interval of 10 years based on population enumerated in different decennial population census since 1901. However, as discussed later, there is a discontinuity in the population growth pattern in India before and after 1951 or before or after the independence in 1947.

Modelling and Forecasting Population Growth

Since the objective is to forecast district population, the population growth modelling exercise is based on the population growth pattern during 1951-2011 only. The population growth model for each district, based on population growth during the period 1951-2011 has than be used to forecast population of the district for the period 2011-2041 through simple extrapolation. The population forecast of districts within a state or Union Territory so obtained has then been added to obtain population forecast of state or Union Territory and then population forecast of the country. It is found that the population forecast for the country obtained through the bottom-up approach adopted in this monograph closely resembles the population projections prepared by the Government of India.

The monograph is divided into five chapters including this introduction. The next chapter of the monograph describes population growth in India and in its constituent states and Union Territories for the period 1901-2011 and for 640 districts as they existed at the time of 2011 population census, for the period 1951-2011. The third chapter outlines the approach that has been followed to model the population growth pattern in districts during the period 1951-2011 and presents results of the population growth modelling exercise for male and female population in each of the 640 districts. The modelling approach is guided by the demographic transition theory that describes the transition of the population from the stage of high stationarity to the stage of low stationarity. Chapter four of the monograph presents forecast of the male and female population in 640 districts and, based on population forecast of districts, population forecast for states and Union Territory and the country. The population forecast for the country and for its states and Union Territories based on the bottom-up approach has also been compared with the official population projections prepared by the Government of India. The last and the concluding chapter of the monograph discusses how age-specific male and female population forecast for the district can be obtained from the forecast of the total male and female population of the district.

Population Growth 1951-2011

According to the Registrar General and Census Commissioner of India, the population of India was enumerated to around 233 million at the 1901 population census which increased to almost 1211 million at the 2011 population census. This means that the population of the country increased by almost 1 billion between 1901 and 2011. There are two distinct phases of population growth in India, before 1951 and after 1951 or roughly before independence and after independence. Between 1901 and 1951, the population of the country increased by just around 116 million to reach 359 million in 1951. However, between 1951 and 2011, the population of the country increased by more than 850 million. The data available from different decennial population census in the country suggest that there is a discontinuity in population growth pattern in India before and after the 1951. The average annual population growth rate in the India has always been less than 1.4 per cent per year during the period 1901-1951. However, there has been a jump in the average annual population growth rate after 1951 or after independence. The average annual growth rate of the population of the country was less than 1.3 per cent per year during the decade 1941-1951 but it jumped to almost 2 per cent per year during the decade 1951-1961 and then to an all-time high of more than 2.2 per cent per year during the decade 1961-1971. After 1971, the average annual population growth rate of the country decreased, but, even during the decade 2001-2011, the average annual population growth rate in the country was more than 1.6 per cent per year, well-above the average annual population growth rate that prevailed in the country before 1951. Reasons for this jump in the average annual population growth rate in the country before 1951 and after 1951 largely remains unexplained. This discontinuity in population growth in the country before and after 1951, however, suggests that the population growth pattern in the country during the period 1901-1951 has been different from the population growth pattern that has been observed after 1951 or after the independence. This discontinuity in the population growth pattern has implications for modelling population growth.

In an attempt to examine the population growth pattern in India during the period 1901-2011, we have carried out the joinpoint regression analysis to the population enumerated at different population census between 1901 and 2011. The joinpoint regression analysis is different from the conventional linear regression analysis in the sense that the joinpoint regression analysis is based on the implicit assumption that the growth of the population has not been uniform during the period under reference but the pace of population growth has been different in different time-segments of the

Modelling and Forecasting Population Growth

reference period, 1901-2011 in the present case. The joinpoint regression analysis, therefore, first identifies the time when the rate of growth in population has changed or the time of inflection in population growth. Once the points of inflection in population growth are identified, linear regression analysis is applied to characterise population growth between two points of inflection assuming that population growth between two points of inflection is linear. The joinpoint regression analysis is very similar to the piece-wise regression analysis. The difference, however, is that points of inflection in the piece-wise regression analysis are set a-priori whereas they are determined by the data in the joinpoint regression analysis. There are different data driven methods to identify points of inflection in the time series data (Kim et al, 2000).

We have used the Joinpoint Regression Program (National Cancer Institute, 2023) to analyse the population growth trend in India during the period 1901-2011. The software requires, a-priori, the maximum number of inflection points in the time series data. If there is no inflection point in the time series data, the joinpoint regression analysis is the same as the simple linear regression analysis. The maximum number of inflection points depends upon the number of observations in the time series. For example, if the maximum number of joinpoints are set at five, then minimum number of observations in the time series data should be 17. The Program provides estimates of annual per cent change (APC)

in the time segments between two successive points of inflexion which gives an idea about how the trend has changed. Details of the methodology of the joinpoint regression analysis are given elsewhere and not repeated here (Kim et al, 2000).

Results of the joinpoint regression analysis of the pattern of population growth in India during the period 1901-2011 are presented in table 1 and the trend in population growth is depicted in figure 1. The weighted BIC method was used to select the joinpoint regression model and the maximum number of inflexion points was set to 2 as there were only 12 observations in the data. The analysis suggests that population growth in India between 1901 and 2011 can be divided into three-time segments: 1901-1921; 1921-1951; and 1951-2011 on the basis of the annual per cent change (APC) in the population. More specifically, the average annual population growth rate in the country during the period 1901-1951 was just around 0.86 per cent per year whereas the average annual population growth rate during the period 1951-2011 was more than 2 per cent per year (Table 2). It is obvious from figure 1 and tables 1 and 2 that population growth in the country during the period 1901-1951 was contrastingly different from that during the period 1951-2011. An analogous situation prevails in the majority of the states and Union Territories of the country (Table 2). These observations confirm that there was a discontinuity in population growth pattern in the country around the year 1951. Reasons for the observed discontinuity in the population growth pattern in the country before and after 1951 are not known. In any case, this discontinuity in the population growth pattern suggests that population growth in the country should be modelled separately for the period 1901-1951 and for the period 1951-2011.

In view of the observed discontinuity in population growth pattern in India before and after 1951, we have modelled the population growth pattern in 640 districts of the country for the period 1951-2011 only and has used the model for forecasting district population for the period 2011-2041. It may, however, be noted that population estimates for the period 1951-2011 have not been made available by the Registrar General and Census Commissioner of India for all 640 districts of the country as they existed at the 2011 population census. In 30 districts, population estimates are available for the period 1961-2011 while in 10 other districts, they are available for the period 1971-2011 only. In all districts of Assam, population estimates for the year 1981 are not available as the population census could not be carried out in Assam in 1981. We have, therefore calculated the population of the districts of Assam for the year 1981 as the average of the population in 1971 and 1991.

The average annual population growth rate, between successive decennial population census from 1951 to 2011, varies widely across districts as may be seen from table 3 and figure 3. During 1951-1961, the average annual population growth rate was at least 2 per cent per year in 262 out of 600 or almost 44 per cent districts of the country for which population estimates are available for the year 1961; population estimates are not available for 40 districts. By comparison, the number of districts where the average annual population growth rate was at least 2 per cent year during 1961-1971 increased to 413 out of 630 districts; population estimates for 10 districts are not available. During 1971-1981, the average annual population growth rate was at least 2 per cent per year in 433 out of 640 or in more than 67 per cent districts of the country. During this decade, the average annual population growth rate was more than 1.5 per cent per year in almost 90 per cent districts of the country. After 1981, the number of districts having average annual population growth rate of at least 2 per cent per year decreased. During 1981-1991, the average annual population growth rate was 2 per cent per year and more in 412 districts of the 640 districts or in more than 64 districts. This number decreased to 293 during 1991-2001 and, during 2001-2011, there were only 171 or less than 27 per cent districts in the country where the average annual population growth rate was at least 2 per cent per year. In 505 or almost 80 per cent districts of the country, the average annual population growth rate decreased during the period 2001-

Modelling and Forecasting Population Growth

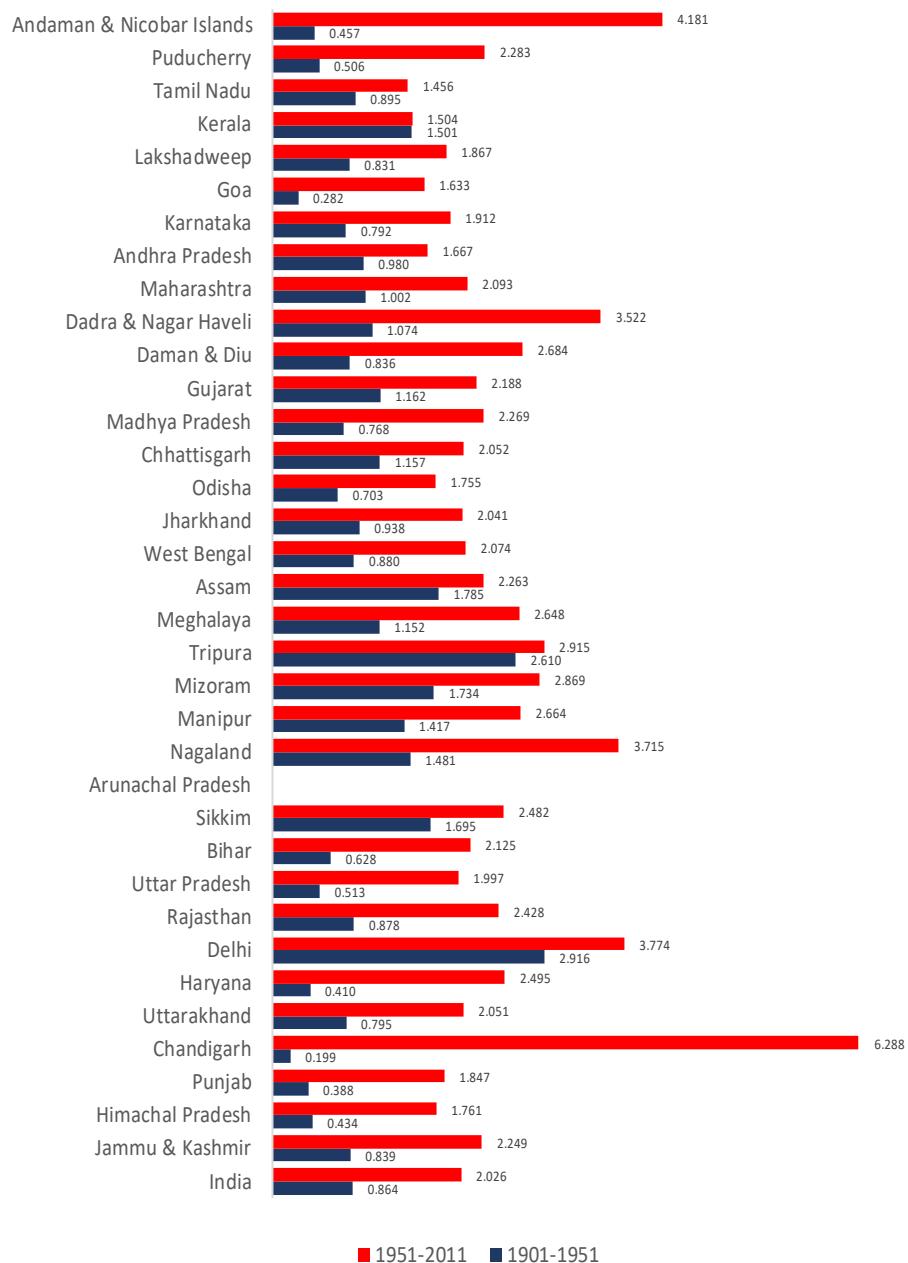

2011 compared to the average annual population growth rate during the period 1991-2001. Similarly, in 69 per cent districts of the country, the average annual population growth rate during the period 1991-2001 decreased compared to the average annual population growth rate during the period 1981-1991. On the other hand, there were 20 districts in the country where the average annual population growth rate was negative during the period 2001-2011 whereas it was less than 0.5 per cent per year in another 20 districts.

Source: Author's calculations based on population count from different population census 1951 through 2011.

Table 3 also shows that the inter-quartile range (IQR) of the inter-district distribution of the average annual population growth rate is very small, but the range is very large. This means that the average annual population growth rate in three-fourth districts of the country varies within a very narrow range but in one fourth districts, it varies widely from the median. During 2011-2011, average annual population growth rate ranged between -8.789 to 7.727 across the 640 districts whereas IQR ranged between 1.142 and 2.050 only. Similarly, the difference between the 10th percentiles and the 90th percentiles of the inter-district distribution of the average annual population growth rate is substantially smaller than the range of the average annual population growth rate across the districts of the country.

An important observation of table 3 is that inter-district distribution of average annual population growth rate was positively skewed till 2001 but turned negative during 2001-2011. A positive skewness means that there are more districts with average annual average population growth rate higher than the mean as compared to the number of districts with average population growth rate less than the mean. Similarly, a negative skewness implies that the number of districts having average annual population growth rate higher than the mean is less than the number of districts having average annual population growth rate less than the mean. Table 3 indicates an important shift in the inter-district distribution of average annual population growth in the country during 2001-2011 as compared to the distribution of average annual population growth rate before 2001. The number of districts having average annual population growth rate more than the mean average annual population growth rate across districts is now less than the number of districts having average annual population growth rate less than the mean of the average annual population growth rate across districts. This means that the number of districts having average annual population growth rate in the country has decreased.

Modelling and Forecasting Population Growth

Table 3 also shows that the excess kurtosis which is a measure of the peak of the inter-district distribution decreased up to 2001 but increased during the period 2001-2011. The decrease in excess kurtosis implies a decrease in the concentration of district average annual population growth rates around the mean of the district average annual population growth rates whereas an increase in the excess kurtosis implies that the concentration of the district average annual population growth rates around the mean average annual population growth rate has increased. Table 3 suggests a divergence in average annual population growth rate across the districts in recent years.

We have measured the inter-district variation in the average annual population growth rate in terms of the index of variation which is defined as

$$IV = \frac{\sqrt{\sum_i (1 - \frac{r_i}{r_m})^2}}{n}$$

where r_i is the average annual growth rate in district i , r_m is the median of r_i , and n is the number of districts. The index of variation is similar to the coefficient of variation (CV) with the arithmetic mean replaced by the median. It is well-known that when the underlying distribution is not statistically normally distributed, then the interpretation of the arithmetic mean and hence the standard deviation and the coefficient of variation is difficult. Table 3 indicates that the inter-district distribution of average annual population growth rate is not statistically normally distributed so that the coefficient of variation (CV) is not the appropriate measure to reflect the inter-district variation in the average annual population growth rate. In case of skewed distributions, median is a more appropriate measure of central tendency of the distribution than the arithmetic mean. Therefore, the index of variation (IV) is more appropriate to measure inter-district variation than the coefficient of variation.

Table 3 shows that the index of variation in the average annual population growth rate across the districts has shown a decreasing trend during the period 1951-1991, but, after 1991, the index of variation in the average annual population growth rate across districts has shown an increasing trend. A decrease in the index of variation reflects convergence of districts around the median of the distribution whereas an increase shows divergence. Table 3 indicates that population growth in the country has increasingly got concentrated in a few districts since 1991 so that the inter-district variation in the average annual population growth rate has increased. There were 135 districts in the country where the average annual population growth rate increased during the period 2001-2011 compared to the average annual population growth rate during the period 1991-2001.

We have also calculated average annual growth rate separately for the male and the female population of each district. The inter-district variation in average annual growth rate in the male population and that in the female population in different decades of the period 1951-2011 is depicted in figure 4 and summarised in table 4. In 157 districts of the country, the male population increased by at least 2 per cent per year during the period 2001-2011 whereas the female population increased by at least 2 per cent per year in 195 districts during the same period. On the other hand, there are 23 districts in the country, the male population decreased, instead increased during this period as the average annual male population growth rate was negative in these districts. By contrast, the average annual female population growth rate during the period 2001-2011 was negative in only 16 districts of the country. The average annual male population growth rate was positive but less than 1 per cent per year in 104 districts of the country during the period 2001-2011 whereas the average annual female population growth rate was positive but less than 1 per cent per year in only 89 districts of the country during this period.

Modelling and Forecasting Population Growth

Summary measures of the inter-district distribution of average annual male population growth rate and average annual female population reveal that inter-district distribution of the average annual male population growth rate has been essentially different from the inter-district distribution of the average annual female population growth rate throughout the period under reference. The median of the average annual male population growth rate was higher than the median of the average annual female population growth rate during the period 1951-1961 but, after 1961, the median of the average annual female population growth rate has always been higher than the median of the average annual male population growth rate with the only exception of the period 1981-1991 when the median of the male population growth rate was higher than that of the female population. A similar pattern can be seen in the inter-quartile range (IQR). However, the IQR in the average annual male population growth rate was higher than the IQR of the average annual female population growth rate during 1951-1961 and during 1981-1991, although the difference during 1981-1991 was marginal. On the other hand, the index of variation in both average annual male population growth rate and average annual female population growth rate decreased up to 1981-1991 but increased thereafter. The increase in the index of variation in the average annual growth rate after 1991 was, however, more rapid in the male population as compared to the female population. In both male and female population, the skewness in the inter-distribution in the average annual growth rate has been very similar and, in both populations, the skewness shifted from positive to negative after 2001. Similarly, the excess kurtosis in the inter-district distribution in average annual growth rate of both male and female population increased quite rapidly after 2001 which indicates increased concentration of average annual growth rates in the districts around the median of the distribution.

It is clear from table 4 that the pattern of growth in the male population has been different from the pattern of growth in the female population in the districts of the country during the period 1951-2011. This difference in the pattern of male and female population growth is expected as it is well known that the demographic determinants of population growth – fertility, mortality, and migration - are different for the male population as compared to the female population. The sex differentials in mortality are well known and are the result of both biological and genetic factors, and social, economic, and cultural factors. On the other hand, the male-female balance at birth, almost uniformly, favours males compared to females. The global average is around 105 male births for every 100 female births. Although, the male-female balance at birth varies widely across population, yet the available evidence suggests that it is only rare that this balance favours females compared to males. The impact of this male bias in the male-female balance at birth has different impact on the growth of male population as compared to the growth of female population. It is also well-known that the pattern of both in- and out-migration is different in the male population as compared to the female population. In any case, the difference in the pattern of male population growth compared to the female population growth suggests that modelling of the pattern of growth in any population should be carried out separately for the male population and for the female population. Modelling of the pattern of growth in the total population, male and female population combined, is not appropriate as the dynamics of male population growth is different from the dynamics of the female population growth within the same population.

Modelling Population Growth

An approach to model population growth may be conceptualised following the demographic transition theory which describes transition of the population from the stage of high stationarity to the stage of low stationarity. The stage of high stationarity is characterised by high birth rate and high death rate so that the difference between the birth rate and the death rate is small and population growth is slow. As transition advances, death rate starts decreasing primarily because of improvements in the living conditions of the people while there is virtually little change in the birth rate or the decrease in the birth rate is faster than the decrease in the birth rate so that the difference between the birth rate and the death rate widens and population growth rate starts accelerating. This acceleration is slow in the beginning but gains momentum with time to reach a stage when the growth in population is the most rapid. Subsequently, the birth rate also starts decreasing while the decrease in the death rate slows down because it has reached very low levels so that the gap between the birth rate and the death rate starts decreasing and population growth starts decelerating, although population continues to grow. At the stage of low stationarity, both birth rate and death rate reach very low levels so that population growth slows down to very low level. During the transition, the rate of population growth follows a bell-shape trajectory which implies that growth of the population follows an S-shaped trajectory which is characterised by an acceleration in population growth rate up to a certain point and then deceleration beyond that point. The bell-shaped trajectory of population growth rate also implies that population cannot continue to grow indefinitely, and it cannot grow beyond a certain limit. Population increases only when the birth rate is higher than the death rate. Population stops increasing when the birth rate is equal to the death rate. On the other hand, population decreases, instead increases, when the birth rate becomes lower than the death rate.

In addition to the growth in population attributed to the change in the birth rate and the death rate, population growth is also influenced by net migration – the net of in-migrants and out-migrants. If the number of in-migrants is greater than the number of out-migrants, the net migration contributes to the increase in population above the increase determined by the difference between the birth rate and the death rate. If the number of in-migrants is less than the number of out-migrants, net migration contributes to decrease the population in addition to the decrease determined by the difference between the birth rate and the death rate. When the number of net migrants is small compared to the increase in population due to the difference between the birth rate and the death rate, migration hardly affects the

Modelling and Forecasting Population Growth

S-shaped pattern of population growth. However, when the number of net migrants constitute a substantial proportion of the increase or decrease in population, the S-shaped pattern of population growth may be different. In such a situation, the pattern of population growth may be described by two S-shaped trajectories of population growth, one reflecting the pattern of population growth attributed to the change in the birth rate and the death rate and the other reflecting the pattern of population growth attributed to net migration.

The S-shaped trajectory of population growth can be characterised by different mathematical models. These models include the logistic growth model, the Gompertz growth model, the generalised logistic growth model, and the modified exponential growth model. The logistic growth model – one of the best-known growth models in demography - is the simplest representation of the S-shaped population growth pattern comprising of an initial period of slow growth, followed by a period of accelerating growth, and finally a period of decelerating growth that approach zero as the population approaches its upper limit. It is very similar to the cumulative normal distribution and is unskewed and symmetric about the point of inflection of the population growth trajectory or the time when the rate of population growth is the maximum. This model was first developed by Verhulst in 1838 (Verhulst, 1838) and later re-invented independently by Pearl and Reed in 1920 (Pearl and Reed, 1920). This model of population growth assumes that population grows exponentially under the constraint of an upper limit (Lotka, 1956). This upper limit may be perceived as the upper limit of population growth.

Application of the logistic growth model to model the growth of population has a long history. It was a popular method of population forecasting in the early days of the twentieth century (Smith and Swanson, 2013). Several studies have shown that logistic growth model may often provide reasonably accurate population forecast (Dorn, 1950; Leach, 1981). In recent years, there is a renewed interest in the logistic growth model to describe and forecast population growth at country and below country levels (Hrytsiuk et al, 2023; Burg and Ausubel, 2023; Mondol et al, 2018; Shariff Ullah et al, 2019). In India, Bhat (1999) had used the logistic growth model to forecast the population of Delhi, the capital city of India. There are also studies which have used other models such as the Gompertz growth model to describe the pattern of population growth (Pflaumer, 2012; Welagedara et al, 2019).

The logistic growth model is defined by the differential equation:

$$\frac{dP}{dt} = rP \left(1 - \frac{P}{K}\right) \quad (1)$$

Where P is the population size, K is the upper limit of population growth, r is the population growth rate and t is the time. The cumulative function associated with equation (1) is.

$$P_t = \frac{K-d}{1+e^{-r(t-t_m)}} + d \quad (2)$$

where

P_t = the population at time t ,

d = lower asymptote

K = upper asymptote of the model

r = intrinsic population growth rate

t_m = the time of inflection or the time when the population reaches half of the upper asymptote.

The intrinsic population growth rate r specifies the “width” or “steepness” of the population growth trajectory. One approach to calculate the intrinsic population growth rate r is based on the time required for the population to grow from 10 per cent to 90 per cent of the parameter K or the upper

asymptote of the model. This time period is termed as the characteristic duration of population growth or Δt . If P_1 is 10 per cent of K or the upper asymptote at time t_1 , then,

$$0.1 = \frac{P_1}{K} = \frac{1}{1+e^{-r(t_1-t_m)}} \text{ or } 9 = \frac{1}{e^{-r(t_1-t_m)}} \quad (3)$$

Similarly, if P_2 is 90 per cent of K or the upper asymptote at time t_2 , then,

$$0.9 = \frac{P_2}{K} = \frac{1}{1+e^{-r(t_2-t_m)}} \text{ or } 9 = e^{-r(t_2-t_m)} \quad (4)$$

Equation (2) and (3) suggest that.

$$9 \times 9 = 81 = \frac{e^{-r(t_2-t_m)}}{e^{-r(t_1-t_m)}} = e^{r(t_2-t_1)} = e^{r \times \Delta t} \quad (5)$$

so that

$$r = \frac{\ln(81)}{\Delta t} \quad (6)$$

The most critical aspect of fitting the logistic growth model (1) is to estimate the parameter K or the upper asymptote of the model. The estimate of the parameter K or the upper asymptote has substantial impact on the forecast based on the logistic growth model (Smith et al, 2013). There are different approaches to estimating the parameter K . These include: i) accelerating growth function method, ii) tangent at the inflexion point method, iii) segmented regression method; iv) modified segmented regression method; v) non-significant difference method; and vi) non-significant difference by simulation method. A description of these methods and how different methods approximate the parameter K is given elsewhere (Passos et al, 2012). In the present analysis, we have used the tangent at the inflexion point method to estimate the parameter K or the upper asymptote of model (1). In this method, the tangent at the inflexion point of the population growth trajectory is taken as a linear approximation of the growth phase of the population before the upper asymptote and the intersection of the tangent at the inflexion point with the upper asymptote gives an approximation of the upper asymptote of the logistic growth model. If Y is the size of the population at the point of intersection of the tangent at the inflexion point with the upper asymptote, then parameter K or the upper asymptote of model can be estimated as (Passos et al, 2012):

$$K = Y \times (1 - \exp(-2)) \quad (7)$$

We have used the open-source Loglet Lab software package (Yung et al, 1999) for fitting the logistic growth model to population growth during 1951-2011 in each of the 640 districts of the country as they existed at the time of the 2011 population census. The Loglet Lab software is designed for decomposing population growth into different S-shaped components which is roughly analogous to the wavelet analysis which is a popular approach in signal processing and compression. When there is only one wave, the wavelet analysis is limited to the analysis of a single S-shaped curve which we adopt in the present analysis. The details of the Loglet Lab software along with the mathematics of the wavelet analysis are described in detail elsewhere (Meyer et al, 1999). The software also provides estimates of mean absolute percentage error (MAPE), goodness-of-fit statistics (RSS and RMS) and the estimate of R^2 which allows to assess the appropriateness of the model in describing the observed district population growth pattern. It may, however, be pointed out that R^2 is not an appropriate measure for ascertaining the goodness-of-the fit for the nonlinear models like the logistic growth model (Spiess and Neumeyer, 2010). However, R^2 can be calculated for the logistic growth model using the Fisher-Pry transformation (Fisher and Pry, 1971).

Modelling and Forecasting Population Growth

Source: Author

The fitting of the logistic growth model to the pattern of population growth during 1951-2011 in 640 districts reveals that there are only 3 districts where the pattern of growth in the male population during 1951-2011 is not described satisfactorily by the logistic growth model as the R² is estimated to be less than 0.80. Similarly, there are 4 districts where the pattern of female population growth is not described satisfactorily by the logistic growth model because of a low value of R². Out of these 7 districts, 4 are in the north-eastern part of the country and 3 are in Nagaland alone. District Diu in the Union Territory of Daman and Diu is the only district in the country where the pattern of growth in both male and female populations during the period 1951-2011 is not found to be described satisfactorily by the logistic growth model.

On the other hand, there are only 10 districts in the country where the mean absolute percentage error (MAPE) in case of the male population is estimated to be at least 10 per cent whereas the MAPE in case of the female is estimated to be at least 10 per cent in only 8 districts. One reason for the relatively unsatisfactory fit of the logistic growth model to the pattern of population growth during the period 1951-2011 in these districts may be rapid increase or decrease in the enumerated population in a decennial population census as compared to the immediately preceding decennial population census. For example, in district Kiphire in Nagaland, the enumerated population more than doubled between the 1991 and the 2011 decennial population census but, the population enumerated at the 2011 decennial population census decreased relative to the population enumerated at the 2001 decennial population census. It appears that net migration appears to have played a dominant role in deciding the population growth instead of the natural population growth that is determined by the trend in the birth rate and the death rate.

On the other hand, there are two districts in the country, both located in the National Capital Territory of Delhi where population growth during the period 1961-2011 has either remained virtually unchanged or has even decreased. In the New Delhi district of the National Capital Territory of Delhi, the population increased from 143846 at the 1961 decennial population census to 179112 at the 2001 decennial population census but decreased sharply to 142004 at the 2011 decennial population census suggesting that there has been virtually no change in the population of the district in 2011 as compared to the population in 1961. Similarly, in the Central district also of the National Capital Territory of Delhi, the population decreased rapidly from 691738 at the 1971 decennial population census to 582320 at the 2011 decennial population census. Because of the typical pattern of population growth in these districts, we have not attempted to fit the logistic growth model (1) to population growth in these districts.

There are 16 districts in the country where both male and female population decreased in 2011 as compared to the population in 2001 according to the 2001 and 2011 decennial population censuses. In addition, there are 7 districts where the male population decreased but the female population increased between 2001 and 2011. Reasons for the decrease in population enumerated at the 2011 decennial population census compared to the population enumerated at the 2001 population census in these districts are not known at present. In any case, it would be interesting to analyse the factors responsible for the decrease in population in these districts during 2001-2011 as revealed through 2001 and 2011 decennial population censuses.

Fitting of the logistic growth model (1) also provides estimates of intrinsic growth rate of male and female population in each district. The intrinsic growth rate of male and female population is not the same within the same district and both the rates also vary across the districts. The inter-district variation in the intrinsic growth rate of the male population and the intrinsic growth rate of the female population is depicted in figure 7 while the summary measures of the inter-district distribution are presented in table 6. In more than half of the districts of the country, the intrinsic growth rate of the male population ranges between 0.074-0.076. There are only 45 or around 7 per cent districts in the country where the intrinsic growth rate of the male population is estimated to be less than 0.074. On the other hand, there are 265 or more than 40 per cent districts of the country, the intrinsic growth rate of the male population is estimated to be at least 0.076. There are 105 districts where the intrinsic growth rate of the male population is estimated to be very high, at least 0.080. In district Kiphire in Nagaland, the intrinsic growth rate of the male population is estimated to be the highest among all districts of the country. In case of the female population, inter-district variation in the intrinsic growth rate is wider than the inter-district variation in the intrinsic growth rate of the male population. In 71 or around 11 per cent districts of the country, intrinsic growth rate of female population is estimated to be less than 0.074 whereas, in 240 or almost 38 per cent districts, it is estimated to be at least 0.076. There are 93 districts where the intrinsic growth rate of the female population is estimated to be very high, at least 0.080. In district Nicobar in the Union Territory of Andaman and Nicobar Islands, the intrinsic growth rate of the female population is estimated to be the highest among the districts of the country.

Modelling Population Growth

The difference in the intrinsic growth rate of the male and the female population within the same district as well as the variation in both male and female intrinsic growth rates across the districts as revealed through the fitting of the logistic growth model provides the empirical justification for the modelling of the male population growth separately from the modelling of the female population growth in the same district. The observation that the intrinsic growth rate of the male population is different from the intrinsic growth rate of the female population in the same district also suggests that, within the same district, male and female population should be forecasted separately, and then male and female population forecast should be added to obtain the forecast of the population of the district. Modelling and forecasting the population of the district (males and females combined) is not the right approach for modelling and forecasting district population growth as the pattern of male population growth and the pattern of female population growth is different within the same district.

The results of the modelling population growth in the 640 districts of the country through the simple logistic growth model are revealing. It is well-known that the districts in India are at different stages of demographic transition and at different levels of social and economic development because of various social, economic, cultural, and economic factors. Despite this very strong and inter-district diversity in the country that has persisted over time, the simple logistic growth model has quite satisfactorily described the population growth pattern in the districts during the 60 years between 1951 and 2011. This reflects the appropriateness of the simple logistic growth model to describe the pattern of population growth. The appropriateness of the simple logistic growth model to population growth pattern in all but a few districts of the country during 1951-2011 also suggests that population growth in India has followed the S-shaped growth trajectory during the 60 years between 1951 and 2011 with only a few exceptions. This observation implies that population growth in the districts of the country can be satisfactorily characterised in terms of the critical parameters of the simple logistic growth model and these critical parameters can be used to forecast district population growth. There are only 3 districts where male population growth during the period 1951-2011 could not be described satisfactorily by the logistic growth model. Similarly, the logistic growth model could not satisfactorily characterise the female population growth during the period 1951-2011 in 4 districts of the country. It appears that there are district specific reasons in these districts because of which the simple logistic growth model has not been able to describe the population growth pattern in these districts during 1951-2011. For the sake of uniformity in our approach of modelling and forecasting district population growth, we have assumed that population growth pattern during 1951-2011 in these districts also follows the S-shaped growth trajectory which can be characterised by the simple logistic growth model.

The results of the population growth modelling exercise presented above provide the empirical basis for forecasting district population based on the critical parameters of the simple logistic growth model employed here. Since the critical parameters of the male population growth model are found to be different from the critical parameters of the female population growth model within the same district, it is imperative to forecast male and female population in the same district separately. The forecast of the district population may then be obtained as the sum of the male and female population forecast. This approach takes into consideration the different pattern of male and female population growth in the district. An additional advantage of forecasting district population in this manner is that it allows forecasting the male-female composition of the population or forecasting the sex ratio of the population in the district. The inter-district variation in the population sex ratio in India is well-known

Modelling and Forecasting Population Growth

for its strength and persistence. There are districts where males substantially outnumber females. There are also districts where females outnumber males as revealed through the data available from the decennial population census. Forecasting male and female population separately allows forecasting the trend in the population sex ratio in the districts of the country.

Population Forecast 2011-2041

The parameters of the model (1), estimated separately for male and female population of each of the 640 districts of the country have been used to forecast male and female population in each district for the period 2011-2041. The forecast of total population of the district has then been obtained as the sum of male and female population forecast for the district. Appendix tables 3 and 4 present respectively the forecast of male and female population in each district while the appendix table 5 presents the forecast of the total population for each of the 640 districts. Appendix tables 6 through 8 present the average annual growth rate of male, female, and total population for five-year periods 2011-2016; 2016-2021; 2021-2026; 2026-2031; 2031-2036; and 2036-2041. Finally, appendix table 9 presents the forecast of population sex ratio, measured as the number of males per 100 females. These forecasts give the first-hand idea of the likely population dynamics in each of the 640 districts in the next 30 years between 2011-2041.

The inter-district variation in the likely average annual growth rate of male, female and total population is depicted in figure 8 and 9 and summarised in table 7. The forecasting exercise suggests that average annual population growth rate will be less than 0.5 per cent per year during the period 2036-2041 in 627 of the 640 districts of the country. There will be 5 districts where the average annual population growth rate during the period 2036-2041 will be at least 1 per cent per year whereas in 2 districts, the average annual population growth rate will be more than 2 per cent per year. On the other hand, the average annual growth rate of the male population will be less than 0.5 per cent per year in 628 districts but in 620 districts in the female population. There will be 5 districts where the average annual growth rate of the male population will be at least 1 per cent per year whereas in 1 district, the average annual growth rate of the male population will be more than 2 per cent per year. In the female population, the average annual growth rate will be at least 1 per cent per year in 3 districts whereas in 2 districts, it will be 2 per cent per year and more. The 5 districts where the population is likely to increase by at least more than 1 per cent per year even during the period 2036-2041 are: district Gurgaon in Haryana, districts Daman and Diu in the Union Territory of Daman and Diu, district Kurung Kumey of Assam and district Yanam in the Union Territory of Puducherry. In districts Kurung Kumey of Assam and district Yanam of the Union Territory of Puducherry, it is the most likely that the population will be growing at an average annual growth rate of more than 2 per cent per year even during the period 2036-2041.

Modelling and Forecasting Population Growth

The population sex ratio, measured as the number of males for every 100 females, based on the forecast of male and female population will also vary widely across the district of the country as may be seen from table 8 and figure 10. The inter-district distribution of the population sex ratio in the year 2011, based on the present modelling exercise is very similar to the inter-district distribution of the population sex ratio based on the male and female population enumerated at the 2011 population census. This similarity in the inter-district distribution in the male-female composition of the population provides another evidence that modelling population growth through logistic growth model provides very good fit to the pattern of male and female population growth across the districts of the country. According to the 2011 population census, there were 97 districts in the country where the population sex ratio was less than 100 males for every 100 females which means that there were more females than males in these districts at the time of the 2011 population census. On the other hand, modelling of male and female population growth during the period 2051-2011, based on the logistic growth model also suggests that there were 99 districts where there were more females than males in the year 2011 as the population sex ratio, based on the model estimates of male and female population in these districts is found to be less than 100 males for every 100 females. Similarly, the data available from the 2011 population census suggest that there were 169 districts in the country where the population sex ratio was highly favourable to males as there were at least 110 males for every 100 females in these districts. On the other hand, the logistic growth model suggests that there were 173 districts in the country where there were at least 110 males for every 100 females in the year 2011.

The median population sex ratio across the 640 districts of the country in was found to be 105 males for every 100 females according to the 2011 population census whereas the median population sex ratio according to the logistic growth model is estimated to be 106 males for every 100 females in the year 2011. The lowest sex ratio, according to the 2011 population census was 84 males for every 100 females in district Mahe of the Union Territory of Puducherry while the highest population sex ratio was 187 males for every 100 females in district Daman in the Union Territory of Damand and Diu. According to the population growth modelling exercise also, the population sex ratio in 2011 was the lowest in district Mahe (85 males for every 100 females) but the highest in district Daman (192 males for every 100 females).

Table 8: Inter-district distribution of population sex ratio (males for every 100 females) in India, 2011-2041.

The district level male and female population forecast also suggests that the number of districts with population sex ratio less than 100 or districts where the number of females are more than the number of males is likely to increase from 97 in 2011 to 140 in 2041. However, there will be virtually little change in the number of districts having population sex ratio between 100-105. Similarly, there will be little change in the number of districts having population sex ratio between 105-110 between 2011 and 2041. The number of districts having population sex ratio between 110 and 115 will, however, decrease from 124 in 2011 to 85 in 2041, but there will be little change in the number of districts having highly masculine population sex ratio as the number of districts having a population sex ratio of more than 115 will decrease only marginally from 45 in 2011 to 38 in 2041. In these districts males will be substantially outnumbering females. The lowest population sex ratio in 2011 was in district Mahe of the Union Territory of Puducherry where there were 84 males for every 100 females according to the 2011 population census and 85 males for every 100 females according to the present modelling exercise. On the other hand, district Daman in the Union Territory of Daman and Diu had the highest population sex ratio in 2011 as there were 187 males for every 100 females according to the 2011 population census whereas 192 males for every 100 females according to the present modelling exercise. In the year 2041 also, the population sex ratio is likely to remain the highest in district Daman in the 2041 and it is likely to increase rapidly to 249 males for every 100 females by the year 2041. On the other hand, district Yanam in the Union Territory of Puducherry is likely to have the lowest population sex ratio among the districts of the country. The population forecast for the district suggests that there will be only around 63 males for every 100 females in the year 2041.

An interesting observation of table 8 is that there will be little change over time in the first quartile, median (second quartile), and third quartile of the inter-district distribution of the population sex ratio in the country. However, the range of the population sex ratio (maximum population sex ratio minus minimum population sex ratio) across the districts of the country is likely to increase from 25 in 2011 to 46 in 2041. This means that in districts where the population sex ratio is currently highly favourable to females or the femininity in the male-female composition of the population is likely to increase further in the coming years. Similarly, in districts where the population sex ratio is currently highly favourable to males or the masculinity in the male-female composition of the population is also likely to increase further in the coming years. The districts which are currently feminine in composition are likely to become more feminine in the years to come. Similarly, the districts which are currently masculine in composition are likely to become more masculine in the coming years. The modelling and forecasting exercise, however, indicates that there will be hardly any substantial change in the inter-district distribution of the population sex ratio in the country in the next 30 years.

The population forecast for the districts, based on the present modelling exercise, also suggests that the population of India is, the most likely, to increase to around 1566 million by the year 2036, and 1582 million by the year 2041. According to the official population projections prepared by the Government of India, the population of the country is projected to increase to around 1521 million by the year 2036 (Government of India, 2022). On the other hand, the medium variant of the population projections prepared by the United Nations Population Division suggests that the population of the country will increase to around 1619 million by the year 1941 (United Nations, 2022). The proximity of the population forecast of the country based on the present modelling exercise with the population projections prepared by the Government of India and by the United Nations Population Division provides the credence to the bottom-up population growth modelling approach adopted in the present exercise. This proximity also implies the appropriateness of the logistic growth model in modelling and forecasting population growth in the districts of the country.

The population forecast for male and female population also suggests that the population sex ratio in the country will decrease from around 106 males for every 100 females in 2011 to around 105 males for every 100 females in 2026 and then will remain virtually unchanged (Table 10). The population sex ratio is likely to increase in the Union Territories of Dadra and Nagar Haveli and Daman and Diu which means that population of these Union Territories will turn increasingly masculine in the years to

come. The increase in the population sex ratio is likely to be very rapid in the Union Territory of Daman and Diu. On the other hand, in Haryana, Himachal Pradesh, Jharkhand, Lakshadweep, Odisha and Punjab, the population sex ratio is likely to remain unchanged during the 30 years between 2011 and 2041. In Andaman and Nicobar Islands, Jammu and Kashmir, and West Bengal also, there is little likelihood of any significant change in the population sex ratio in the coming years. In other states and Union Territories of the country, the likelihood is that the population sex ratio will turn increasing favourable to females, although the pace of decrease in the population sex ratio will be different in different states and Union Territories. In 2011, the population sex ratio was favourable to females in Kerala and Puducherry only. By the year 2041, the population sex ratio is likely to turn favourable to females in 7 states and Union Territories – Arunachal Pradesh, Kerala, Meghalaya, Mizoram, Nagaland, Puducherry, and Tamil Nadu.

The upper asymptote of the logistic growth model gives the upper limit of growth of the S-shaped growth trajectory. This means that adding the upper asymptote of all the 640 districts gives an estimate of the upper limit of the population growth in the country. This exercise suggests that the upper limit of the male population growth in the country, most likely, will be around 828 million whereas the upper limit of the female population growth, most likely, will be around 792 million. This means that, according to the present modelling exercise, it is the most likely that the upper limit of the population growth in India will be around 1620 million. This implies that it is the most likely that maximum addition to the population of the country will be around 409 million which is more than the population that the country had in 1951. Results of the modelling exercise also permit to estimate the most likely upper limit of population growth in the states and Union Territories of the country also.

The population projections prepared by the Government of India do not provide any estimate of the upper limit of the population growth India as the projection exercise is limited to the projection horizon of 25 years only. However, the population projections prepared by the United Nations Population Division suggest that the population of the country will increase to around 1532 million according to the low variant of the population projection and to 1697 million according to the medium variant of the population projection. On the other hand, the high variant of population projection prepared by the United Nations Population Division suggests that the population of the country will continue to increase throughout the current century and will reach around 2251 million by the year 2100 (United Nations, 2022). The likely upper limit of population growth of the country projected by the United Nations Population Division is contingent upon the assumption about the pace of decrease in the level of fertility in the coming years. The United Nations population Division assumes that the pace of mortality transition will remain the same in all the three variants of population projection. A comparison of the upper limit of population growth in India obtained through the modelling of district population growth with that of the projections prepared by the United Nations Population Division shows that the upper limit of population growth in India estimated through the modelling of district population growth during the period 1951-2011 is a very close approximation of the upper limit of the population growth in the country as revealed through the medium variant of the population projection prepared by the United Nations Population Division. The difference may be attributed to the fact that the projections prepared by the Union Ted Nations Population Division takes into account the population migrated out of the country and the net omission rate in population enumeration during census. In the bottom-up approach adopted in the present modelling exercise, it is not possible to adjust the population enumerated in the districts at different population census because the relevant information is not available. In any case, there is a difference of only around 3 per cent in the upper limit of population growth estimated through the present modelling approach and the upper limit of

Modelling and Forecasting Population Growth

population growth projected by the United Nations Population Division. This close proximity of the population forecast for India and its constituent states and Union Territories based on the modelling of population growth in the districts of the country during the period 1951-2011 with population projections produced by the Government of India and United Nations Population Division reflects the appropriateness of the bottom-up approach of population forecasting in which population forecast is first produced for the smallest area or the lowest level administrative unit. It is obvious that the logistic model of population growth describes, very satisfactorily, the population growth dynamics in all but a few district of the country so that the population forecast for the country and for its constituent states and Union Territories obtained by adding the forecast of the population of districts is in very close approximation of population projections produced by the Government of India and the United Nations following different approaches of population projections. The advantage of the present bottom-up approach of modelling and forecasting population growth is that it takes into account the population growth dynamics at the district level. Given the diversity of the country India in all dimensions or demographic and development, it is obvious that the population growth dynamics is different in different districts of the country. Another advantage of the model-based approach of population forecasting is that the forecasting can be done even up to the lowest level of the administration – village in the rural areas and towns in the urban areas – subject to the availability of village population counts from different population census.

Conclusions

Forecasting or projection population of districts has been a grossly neglected area in demographic research in India. This is so when updated estimates of population is a necessity for district development planning and programming that has been emphasised in the country since long. The only source of information about demographic situation in the districts of the country has been the decennial population census as the official sample registration system does not provide estimates of selected vital rates at the district level and the civil registration system of the country is fraught with conceptual and operational problems. It is for the first time that India could not conduct the decennial population census in time since 1901 because of the COVID-19 pandemic. The absence of the decennial population census in 2021 has, however, left a demographic void at the district level in the country. To fill up this void, it is necessary to at least project or forecast district population.

It is in the above context that the present monograph presents population forecast for 640 districts of the country as they existed at the time of the 2011 population census based on the modelling of population growth in each district during the period 1951-2011. The modelling is based on the assumption that population in the districts of the country has followed the S-shaped growth trajectory which has been captured through the logistic growth model. This modelling of population growth in the districts of the country could be possible because the Registrar General and the Census Commissioner of India has provided, for the first time, population counts for 640 districts of the country at different decennial population census beginning 1901. The present exercise has, however, been based on the population growth in the districts during the period 1951-2011 or the period since independence as the discontinuity in population growth in India before and after 1951 or before and after the independence is well-known so that population growth model during the period prior to 1951 is different from the population growth model after 1951.

The modelling exercise has revealed that the logistic growth model provides a very good fit to the population growth in all but a few districts of the country during the period 1951-2011 which means that population growth in the districts has followed an S-shaped trajectory during the period 1951-2011. The very finding that the logistic growth model provides a good fit to population growth in most of the districts of the country during the period 1951-2011 has constituted the basis for forecasting population of districts by the extrapolation of the model for the period 2011-2041. It has been found that the district

Modelling and Forecasting Population Growth

population forecast, based on the logistic growth model, lead to population forecast at state/Union Territory and country level which is very similar to population projections prepared by the Government of India. This similarity in the likely population growth in the confirms the veracity of the model-based bottom-up forecasting approach.

The present modelling exercise provides forecast of male and female population in every district of the country as male and female population counts have been provided by the Registrar General and Census Commissioner of India. However, the exercise does not provided forecast of district population by age which is a standard requirement for any demographic analysis. There are two possibilities of forecasting district male and female population by age using the forecast of male and female population of the district presented here. The first possibility is to apply the raking method or the method of interactive proportional fitting or the contingency table method (Arriaga et al, 1994) along with the male and female population forecast presented in this monograph. The male and female population forecast for the district may be used as control and the raking method may be applied to obtain male and female population forecast by age. The age-specific male and female population forecast may then be added to obtain age-specific population forecast for the total population of the district.

The second possibility is based on the observation that the age composition of the population also changes with the demographic transition. It is well-known that as the demographic transition advances, there is a shift in the age composition of the population. At the early stages of demographic transition, the age-sex population pyramid is triangular with a broad base and a thin top. As the transition advances, the shape of the population pyramid changes which means that the proportionate distribution of the population by age changes. At very advance stage of demographic transition, the triangular shape of the population pyramid is reversed. This suggests that empirical patterns of population age composition at different level of population growth rate can be established, and these empirical patterns can be used to forecast the age composition of male and female population corresponding to the forecast of future male and female population.

The model-based approach to population forecasting is a dynamic exercise. The new data from census or from any other source about district population growth leads to the evolution of new model of population growth pattern and hence a new set of population forecast.
